Measurement of branching fractions of $B$-meson decays to final states containing an $\eta'$ and a vector meson

ALAN ROBERTSON, University of Edinburgh, BABAR COLLABORATION — We present branching fraction results for charged and neutral $B$ decay modes to charmless, quasi-two body, final states containing $\eta'K^*$ and $\eta\rho$. The results are compared to theoretical predictions and provide information on the suppressed magnitude of $\eta'K^*$ with respect to enhanced $\eta'K^*$ decay channel. The results are derived using a multivariate maximum likelihood fit using data recorded by the BaBar detector, which comprise an integrated luminosity of 210.5 fb$^{-1}$ corresponding to 232 million $\bar{B}B$ pairs.
