Search for H Decays to WW* at CDF SUSAN BURKE, ERIC JAMES, Fermi National Accelerator Laboratory, CDF COLLABORATION — We present a search for Standard Model Higgs production in proton-antiproton collisions at sqrt(s)=1.96 TeV using approximately 2.4 fb^{-1} of data collected with the CDF II detector. We consider the diboson decay channel, H→WW*, which is the dominant decay mode for Higgs masses above 140 GeV/c^2. We further require both W bosons to decay leptonically. Both single and associated Higgs production modes are considered. In order to maximize sensitivity, a combined Matrix Element method and Neural Network approach is utilized to distinguish signal from background processes. Cross-section limits are presented for Higgs mass hypotheses between 110 GeV/c^2 and 200 GeV/c^2.
