The Axion Dark Matter eXperiment Cryogenic System  

HANNAH LETOURNEAU, University of Washington, ADMX COLLABORATION — The Axion Dark Matter eXperiment (ADMX) searches for dark matter axions by looking for their resonant conversion to photons in a microwave cavity in a high magnetic field. The mass of the axion (unknown) determines the frequency at which the axion couples to the magnetic field, so the cavity is tuned through a wide range of frequencies while measuring the power deposited in it with ultra-sensitive quantum electronics. The dominant systematic noise is from the noise temperature of the electronics; during the last data run they were cooled to 1.5K with a pumped He-4 refrigerator. Currently, we are installing a large dilution refrigerator, which will cool the cavity and first stage amplifiers to \( \approx 100 \text{ mK} \). I will discuss our progress, describe some of the challenges we have faced and how we have overcome them, and describe our plans for operation.
