Detection of far ultraviolet radiation by wavelength-shifting tetraphenyl butadiene

JOSHUA R. GRAYBILL, CHANDRA B. SHAHI, MICHAEL C. COPLAN, University of Maryland, ROBERT E. VEST, ALAN K. THOMPSON, National Institute of Standards and Technology, CHARLES W. CLARK, Joint Quantum Institute — Far ultraviolet (FUV) radiation has been used in low-energy particle physics\(^1\), dark matter searches\(^2\), and neutron detection\(^3\), in conjunction with wavelength-shifting (WLS) materials. Tetraphenyl butadiene (TPB) has been found to have high conversion efficiency compared to other WLS fluorophores. We have spin-coated TPB films with high uniformity and optical quality on glass windows and compared the absolute efficiencies of both the spin-coated and vapor deposited films over the incident radiation wavelengths 120 nm < \(\lambda\) < 400 nm at the NIST SURF III Synchrotron Ultraviolet Radiation Facility. While photon efficiencies of 0.7 and 1.35, have been reported\(^4\), our preliminary results indicate the absolute efficiencies to be between 0.2 and 0.5. The Neutron Observatory\(^5\) was used to compare conversion efficiencies in well-characterized detector platforms.
