An Independent Measurement of $H_0$ from Lensed Quasars$^1$
KENNETH WONG, Univ of Tokyo

Strong gravitational lens systems with time delays between the multiple images are a powerful probe of cosmology, particularly of the Hubble constant ($H_0$) that is key to probing dark energy, neutrino physics, and the spatial curvature of the Universe, as well as discovering new physics. The $H_0$ Lenses In COSMOGRAILs Wellspring (H0LiCOW) project has measured $H_0$ from lensed quasars using deep Hubble Space Telescope and AO imaging, precise time delay measurements from the COSMOGRAIL monitoring project, a measurement of the velocity dispersion of the lens galaxies, and a characterization of the mass distribution along the line of sight. Our latest results from a total of six lenses constrains $H_0$ to be $73.3^{+1.7}_{-1.8}$ km/s/Mpc for a flat Lambda CDM cosmology, which is a measurement to 2.4
