Electron impact ionization of magnesium.¹ DANIEL WEFLEN, XI-AOXU GUAN, KLAUS BARTSCHAT, Drake University — We have applied a hybrid method, combining a second-order distorted-wave method for a fast ionizing projectile with an \( R \)-matrix (close-coupling) approach for the initial bound state and the ejected electron [1], to calculate electron impact ionization of magnesium. Our results will be compared with recent experimental data [2] and predictions from other theoretical approaches [3]. For various kinematical situations, in-plane and out-of-plane, we analyze the sensitivity of the theoretical results to the details of the computational model. We will suggest additional benchmark experiments to test the various theoretical approaches.
