Abstract Submitted for the DAMOP08 Meeting of The American Physical Society

Dissociative Electron Attachment to HCCCN¹ S.T. CHOUROU, A.E. OREL, Department of Applied Science, University of California, Davis — Experiments on dissociative electron attachment (DEA) to HCCCN below 12 eV have led predominantly to formation of CCCN⁻, CN⁻, HCC⁻ and CC⁻ negative ions. It has been concluded that these fragments result mainly from the decay of π^* - shape resonant state upon electron attachment that involves distortion of the symmetry of the linear neutral molecule. In order to study the dynamics of dissociation in these channels, we subdivided the molecule into three fragments (H), (CC) and (CN); therefore, three internal coordinates consisting in the distances between the center of masses (H) and (CC) fragments, (CC) and (CN) fragments and the (H)-(CC)-(CN) angle are included in the calculation. We have performed electron scattering calculations using Complex Kohn Variational method to determine the resonance energies and autoionization width for various geometries of the system and construct the complex potential energy surfaces relevant to the metastable HCCCN^{-*} ion. The nuclear dynamics is treated using the Multiconfiguration Time-Dependent Hartree (MCTDH) formalism and the flux of the propagating wavepacket is used to compute the DEA cross section relevant to 4 channels in question. The results are then compared to the available findings.
