A possible Efimov trimer in 3-component lithium 6

PASCAL NAIDON, JST, MASAHITO UEDA, JST, University of Tokyo — We consider the Efimov trimer theory as a possible framework to explain recently observed losses by inelastic three-body collisions in a three-hyperfine-component ultracold mixture of lithium 6. Our results show that such a trimer state is indeed possible given the two-body scattering lengths in the three-component lithium mixture, and gives rise to two zero-energy resonances. The locations of these resonances appear to be consistent with observed losses. This would be the first observation of an Efimov trimer of distinguishable fermions.
