Optical Control of Collisional Interactions in $^6$Li using Dark Molecular States

ARUNKUMAR JAGANNATHAN, Duke University, NITHYA ARUNKUMAR, North Carolina State University, ETHAN ELLIOT, Duke University, JAMES JOSEPH, JOHN THOMAS, North Carolina State University — We are developing “dark-state” two-optical field methods to control interactions in $^6$Li. Although external magnetic fields are typically used to tune the interaction strength in fermionic atoms near a Feshbach resonance, optical tuning methods can provide rapid temporal control and high-resolution spatial control thus enabling the study of non-equilibrium strongly interacting Fermi gases. However, optical tuning suffers from heating due to spontaneous scattering, which can be suppressed by a second optical field. We will report on the measurement of loss spectrum as a function of magnetic field and laser detuning near Feshbach resonances in $^6$Li and our progress on two-optical field loss suppression.
