Time-dependent local density approximation study of attosecond time delays in the photoionization of xenon.\textsuperscript{1} MAIA MAGRAKVELIDZE\textsuperscript{2}, Northwest Missouri State University, Maryville, USA, MOHAMED MADJET, QEERI, Hamad Bin Khalifa University, Doha, Qatar, HIMADRI CHAKRABORTY, Northwest Missouri State University, Maryville, USA — We investigate Wigner-Smith (WS) time delays of the photoionization from various subshells of xenon using the time-dependent local density approximation (TDLDA) \cite{1} with the Leeuwen and Baerends exchange-correlation functional. At the 4d giant dipole resonance region as well as near all the Cooper minimum anti-resonances in 5p, 5s and 4d photoemissions, effects of electron correlations uniquely determine the shapes of the emission quantum phase. The Wigner-Smith time delay derived from this phase indicates significant variations as a function of energy. The results qualitatively support our TDLDA predictions at the fullerene plasmon region \cite{2} and at 3p Cooper minimum in argon \cite{3}, and should encourage attosecond measurements of Xe photoemission via two-photon interferometric techniques, such as RABITT. \cite{1} M.
