Decoherence Spectroscopy Theory and Application with an Atom Interferometer

RAISA TRUBKO, ALEXANDER CRONIN, University of Arizona

— We developed decoherence spectroscopy as a method to improve the accuracy of a tune-out wavelength ($\lambda_{\text{zero}}$) measurement made with atom interferometry. Specifically, we used atom interference fringe contrast loss as a function of laser frequency in order to monitor Doppler shifts. This was particularly helpful since we used a multi-pass cavity to recycle laser light in this experiment. The resulting decoherence spectra have non-intuitive features. Therefore we present a theoretical model for decoherence spectroscopy and compare this model to several empirical examples.
