Cross Sections and Spin Asymmetries for Electron Collisions with Lead.¹ M. VAN ECK, K. MCNAMARA, D. V. FURSA, I. BRAY, Curtin University, O. ZATSARINNY, K. BARTSCHAT, Drake University — We present angle-integrated and angle-differential cross sections as well as spin asymmetries for elastic and inelastic electron collisions with lead atoms. The results were obtained using the fully relativistic convergent close-coupling (RCCC) [1] and the Dirac B-spline R-matrix (DBSR) [2] methods. They will be compared with experimental data and predictions from previous calculations. In particular, the spin asymmetries for the optically forbidden inelastic transitions from the $(6p^2)^3P_0$ ground state to other states of the $6p^2$ manifold, measured by Geesmann *et al.* [3], are known to be very challenging for theory [2]. We analyze the sensitivity of the predictions to the quality of the target description as well as the number of channels included in the close-coupling expansion. [1] D. V. Fursa and I. Bray, Phys.
