Testing the Standard Model with Electron Dipole Moments

GERALD GABRIELSE, Northwestern University

Our new ACME measurement of the electron electric dipole moment* has a sensitivity greater than past measurements by a factor of 12. The result is consistent with the standard model prediction rather than supersymmetric models, for example. Meanwhile, our measurement of the electron magnetic dipole moment** agrees with the standard models most precise prediction to a part in $10^{12}$, though there is now a 2.4 standard deviation separation of measurement and prediction. A new measurement has been started.
