Manipulating Leidenfrost temperature with surface texture
HYUK-MIN KWON, JAMES BIRD, KRIPA VARANASI, Massachusetts Institute of Technology — When a drop contacts a surface that is at a sufficiently high temperature, the drop can float on its own vapor in a process known as the Leidenfrost effect. Although it is known that the critical temperature needed to achieve this effect depends on the properties of the drop and its vapor, often these parameters are fixed for a particular process. Here, we demonstrate a new way to control the critical temperature through the surface structure.
