Deformation of a single red blood cell in bounded Poiseuille flows[1]

LINGLING SHI, TSORNG-WHAY PAN, ROLAND GLOWINSKI, University of Houston — An immersed boundary method (IBM) combined with the elastic spring model is applied to investigate the deformation of a single red blood cell (RBC) in two-dimensional bounded Poiseuille flows. The equilibrium shape of the cell under flow depends on the swelling ratio ((s^*)), the initial angle of the long axis of the cell at the centerline (φ), the maximum velocity of the flow ($u_{\max}$), the membrane bending stiffness of the RBC (k_b), and the height of the microchannel(H). Two motions of oscillation and vacillating breathing of the RBC are observed in narrow channel considered here. The strength of the vacillating-breathing motion depends on degree of confinement and $u_{\max}$. For the different k_b, the RBC obtains the same equilibrium shape for the same capillary number. Parachute shape and bullet-like shape, depending on the angle φ, coexist for the elliptic shape cell with lower $u_{\max}$ in a narrower channel.
