Large Eddy Simulation of Mixing within a Hypervelocity Scramjet Combustor DAVID PETTY\textsuperscript{1}, VINCENT WHEATLEY\textsuperscript{2}, University of Queensland, CARLOS PANTANO\textsuperscript{3}, University of Illinois at Urbana-Champaign, MICHAEL SMART\textsuperscript{4}, University of Queensland — The turbulent mixing of parallel hypervelocity \((U = 3230 \text{ m/sec, } M = 3.86)\) air-streams with a sonic stream of gaseous hydrogen is simulated using large eddy simulation. The resultant mixing layers are characterized by a convective Mach number of 1.20. This configuration represents parallel slot injection of hydrogen via an intrusive centerbody within a constant area rectangular combustor. A hybrid shock-capturing/zero numerical dissipation (WENO/TCD) switch method designed for simulations of compressible turbulent flows was utilized. Sub-grid scale turbulence was modeled using the stretched vortex model. Visualizations of the three dimensional turbulent structures generated behind the centerbody will be presented. It has been observed that a span-wise instability of the wake behind the centerbody is initially dominant. Further downstream, the shear-layers coalesce into a mixing wake and develop the expected large-scale coherent span-wise vortices.
