Buoyancy induced modification of the law-of-the-wall in an un-stably stratified turbulent channel flow

FEDERICO TOSCHI, Eindhoven University of Technology, ANDREA SCAGLIARINI, University of Rome Tor Vergata, HALLDOR EINARSSON, ARMANN GYLFASON, School of Science and Engineering, Reykjavik University — We present results on the influence of buoyancy on the boundary layer dynamics and on mean quantities, like velocity profiles, in an un-stably stratified turbulent channel flow. The study is based on direct numerical simulations where we investigated a broad range of friction Reynolds numbers and Rayleigh numbers. We primarily focused on the modification of the logarithmic law of the wall, due to buoyancy, and we provide a simple phenomenological model that is able to capture the observed deviations, in the log-law region, from the usual neutral case.
