Influence of Diurnal Heating on a Stratified Open Channel Flow

CINDY NGUYEN-DANG, NICHOLAS WILLIAMSON, STEVEN W. ARMPFIELD, School of Aerospace, Mechanical and Mechatronic Engineering, The University of Sydney, NSW 2006, Australia, STUART E. NORRIS, Department of Mechanical Engineering, The University of Auckland, Auckland 1010, New Zealand, MICHAEL P. KIRKPATRICK, School of Aerospace, Mechanical and Mechatronic Engineering, The University of Sydney, NSW 2006, Australia — This study employs direct numerical simulation (DNS) to investigate stably stratified open channel flows that are subjected to a time-varying surface radiative forcing whose function is approximated by a diel solar heating cycle. This paper follows from the earlier work of a statistically steady state open channel flow with a constant heat source. The simulations have a Prandtl number Pr of 1 and a friction Reynolds number Re_τ of 400. Its bulk buoyancy parameter λ of 1, defined by the ratio of the channel depth δ and a bulk Obukhov length scale L , corresponds to strongly stratified conditions and the diurnal timescales, normalised by the wall friction velocity u_τ over δ , cover the range between $t^* = 6 - 12$. Results demonstrate strong mixing and re-stratification during the night and day heating cycle. Numerical results have been found to be in agreement with existing parameterisation and scaling relations for the irreversible flux Richardson number Ri_f^* and turbulent Froude number Fr and eddy diffusivity k_h and local buoyancy Reynolds number Re_b at certain positions along the water column.
