$^{30,31}$S level structure measured via $(p, t)$ and $(p, d)$ reactions on $^{32}$S

D.W. BARDAYAN$^1$, J.C. BLACKMON, W.R. HIX, J.F. LIANG, L.F. ROBERTS, M.S. SMITH, ORNL, Z. MA, U. Tenn., R.L. KOZUB, Tenn. Tech. U., K.L. JONES, J.S. THOMAS, Rutgers, R.J. LIVESAY, Col. School of Mines, R.P. FITZGERALD, D.W. VISSE, U. North Carolina — An accurate knowledge of the level structure of $^{30,31}$S above the proton threshold is important for calculating the astrophysical rates of proton capture on $^{29,30}$P respectively. These proton captures affect the Si abundances observed in meteoritic presolar grains and the reaction flow to heavier nuclei in novae. We have studied $^{30,31}$S by bombarding ZnS targets with $\sim$40-MeV proton beams from the Holifield Radioactive Ion Beam Facility and detecting reaction tritons and deuterons in the Silicon Detector Array (SIDAR). A total of 13(26) states were observed in $^{30}$S($^{31}$S) including 9(17) above the proton threshold. The spins of strongly-populated levels were constrained through a DWBA analysis of the measured angular distributions. The method and results will be presented.
