Evidence for Multiple Negative-Parity Band Structure in $^{71}\text{Se}$

N.R. BAKER, R.A. KAYE, S.R. ARORA, Ohio Wesleyan University, J.K. BRUCKMAN, Monmouth College, S.L. TABOR, T.A. HINNERS, C.R. HOFFMAN, S. LEE, Florida State University, J. DÖRING, BFS (Germany) — The negative-parity bands of $^{69}\text{Se}$ and $^{73}\text{Se}$ indicate a stark contrast between strong single-particle ($^{69}\text{Se}$) and collective ($^{73}\text{Se}$) behavior over a wide range of spins. However, only one negative-parity band has been observed so far in $^{71}\text{Se}$, making it difficult to see where it lies between these two very different cases. Thus, the goal of the present work was to extend the level scheme of $^{71}\text{Se}$ as much as possible, with an emphasis on finding new negative-parity states. $^{71}\text{Se}$ nuclei were produced at high spin following the 80-MeV $^{54}\text{Fe}$ ($^{23}\text{Na}, \alpha p n$) reaction at Florida State University. $\gamma - \gamma$ coincidences were measured using an array of 10 Compton-suppressed Ge detectors which included three Clover detectors. From the coincidence relationships, new states were found that formed candidates for perhaps two new negative-parity bands. Cranked-shell model calculations indicate that one new band is associated with rigid-body rotation at high spin.
