Study of the $^{19}\text{O}(d,p)$ reaction in inverse kinematics with HELIOS\textsuperscript{1} C.R. HOFFMAN, M. ALCORTA, B.B. BACK, S.I. BAKER, P.F. BERTONE, J.A. CLARK, B. DIGIOVINE, B.P. KAY, R.C. PARDO, K.E. REHM, J.P. SCHIFFER, ANL, C.M. DEIBEL, ANL/JINA, S.T. MARLEY, J.C. LIGHTHALL, ANL/WMU, S. BEDOOR, D.V. SHETTY, A.H. WUOSMAA, WMU, S.J. FREEMAN, D.K. SHARP, J.S. THOMAS, U of Manchester, A. ROJAS, D. SANTIAGO-GONZALEZ, I. WIEDENHÖVER, FSU — The neutron single-particle components of states in $^{20}\text{O}$ have been probed through the $(d,p)$ reaction in inverse kinematics. The experiment consisted of a 125 MeV radioactive $^{19}\text{O}$ beam, produced by the ATLAS In-Flight facility at Argonne National Laboratory, impinging on a $[(\text{C}_2\text{D}_4)_n]$ target located inside the HELical Orbit Spectrometer (HELIOS). A Q-value resolution of $\sim 150$ KeV was achieved for states in $^{20}\text{O}$. Absolute cross sections and angular distributions have been determined for a number of levels in $^{20}\text{O}$ up to 7 MeV in excitation energy. A strong candidate for the previously unobserved $\ell = 0 \ 3^+$ level at 5.2 MeV has been identified. The extracted spectroscopic factors for $\ell = 2$ (presumably $\nu d_{5/2}$) and $\ell = 0$ ($\nu s_{1/2}$) transitions will be compared to those along the $Z = 8$ isotopic chain and to microscopic calculations.
