The fusion of $^{11}\text{Li}$ with $^{208}\text{Pb}$

WALTER LOVELAND, Oregon State University, Corvallis, OR 97331, USA, A.M. VINODKUMAR, Department of Physics, University of Calicut, Kerala, India-673635, R. YANEZ, M. LEONARD, L. YAO, Oregon State University, Corvallis, OR 97331, USA, P. BRICAULT, M. DOMBSKY, P. KUNZ, J. LASSEN, A.C. MORTON, D. OTTEWELL, D. PREDDY, M. TRINCZEK, TRIUMF, Vancouver, British Columbia, V6T 2A3, Canada — We studied the fusion of $^{11}\text{Li}$ with $^{208}\text{Pb}$ at TRIUMF. The intensity of the $^{11}\text{Li}$ beam (chopped) was 1000 p/s and the beam on-target time was 114 hours. The stacked foil technique was used to step the beam energies from 40 to 29 MeV ($E_{c.m.} = 27$-$38$ MeV) throughout the array. The $\alpha$-decay of the stopped EVRs was detected in a $\alpha$-detector array at each beam energy in the beam-off period. The geometrical efficiency of detection of the decay $\alpha$-particles has been calculated to be 0.4. To verify this, we measured the evaporation residue yield for the well-known $^7\text{Li} + ^{209}\text{Bi}$ reaction. We have previously measured the evaporation residue cross sections when $^9\text{Li}$, the $^{11}\text{Li}$ core, fuses with $^{208}\text{Pb}$. We also have done HIVAP calculations of what we might expect for evaporation residue cross sections if $^{11}\text{Li}$ were to fuse with $^{208}\text{Pb}$ rather than breakup. The At isotope patterns observed on-line are not those observed for the $^9\text{Li} + ^{208}\text{Pb}$ reaction but are consistent for expectations of complete fusion.
