Search for $^{90}$Sr from the Fukushima Reactor Accident in San Francisco Bay Area Rainwater

B.T. LO, P.A. CHODASH, K.J. THOMAS, E.B. NORMAN, Univ. of California at Berkeley — Shortly after the Fukushima reactor accident, we collected rainwater samples in the San Francisco Bay area. Subsequent gamma-ray counting revealed the presence of volatile short-lived fission fragments such as $^{131,132}$I, $^{132}$Te, and $^{134,137}$Cs [1]. Recently, we have searched for the presence of the long-lived fission fragment $^{90}$Sr in these same rainwater samples. To chemically separate Sr, a small amount of stable Sr carrier was dissolved in each rainwater sample. Potassium carbonate was then added to precipitate SrCO$_3$. The precipitate was filtered, dried, and then beta counted using a planar Ge detector. Results from these measurements will be presented and compared to the levels of other fission fragments previously observed in the rainwater.
