REHM, Argonne National Laboratory, P.F. BERTONE, Louisiana State University — We have studied the $^{14}\text{B}$ nucleus employing the $^{15}\text{C}(d, ^3\text{He})^{14}\text{B}$ reaction in inverse kinematics using HELIOS (the HELical Orbit Spectrometer) at the ATLAS facility at ANL. A $^{15}\text{C}$ beam was produced using the In-Flight method. The $^3\text{He}$ particles were detected with HELIOS. The recoiling $^{13}, ^{14}\text{B}$ nuclei were identified in a set of silicon $\Delta E$–$E$ telescope, distinguishing bound and unbound states in $^{14}\text{B}$. From a previous study of the $^{13}\text{B}(d, p)^{14}\text{B}$ reaction the $(2_1^-, 1_1^-)$ states were found to be admixtures of $\ell = 0$ and $\ell = 2$ made up of $\pi(0p_{3/2})^{-1} - \nu(1s_{1/2})$ and $\pi(0p_{3/2})^{-1} - \nu(0d_{5/2})$ configurations. The $(2_2^-, 1_2^-)$ excited states were not observed. A complementary reaction can identify the $(2_2^-, 1_2^-)$ states in order to track the single particle strength in $^{14}\text{B}$. In the current study, proton removal from $^{15}\text{C}$ explores only the $\pi(0p_{3/2})^{-1} - \nu(1s_{1/2})$ component of states in $^{14}\text{B}$. The results provide a determination of $2_2^-$ energy level and better constrain the $1s_{1/2}$ and $0d_{5/2}$ effective single–particle energies in $^{14}\text{B}$.
