Prompt and Delayed Spectroscopy of Ac isotopes around $N=126$

S.S. HOTA, G.J. LANE, M.W. REED, A.J. MITCHELL, A.E. STUCHBERY, T. KIBEDI, A.A. AKBER, T.E. ERIKSEN, M.S. GERATHY, N. PALALANI, T.R. PALAZZO, Australian National University — Nuclei above $Z=82$ and around $N=126$ are well described by the spherical shell model, with the attractive proton-neutron residual interactions and particle-octupole vibration coupling resulting in energy-favored, isomeric states occurring along the yrast line. Nuclei up to $Z=88$ are mostly well known [1], but information on Ac ($Z=89$) isotopes is limited. We report on high-spin, gamma-ray spectroscopy measurements of $^{214,215,216,217}$Ac performed at the Australian National University using the CAESAR array and fusion-evaporation reactions between $^{12}$C and $^{14,15}$N beams delivered by the 14UD accelerator incident on $^{204}$Pb and $^{209}$Bi targets. States up to $29/2^+$ isomers were known previously in $^{215,217}$Ac [2,3], while only one gamma-ray has been assigned to each of $^{214,216}$Ac. New level schemes have now been constructed for $^{214,216}$Ac and those for $^{215,217}$Ac have been significantly extended. The results will be presented in detail together with semi-empirical shell model calculations that support the proposed level schemes.
