ECH Density Pumpout and Small Scale Turbulence in DIII-D¹

K.-L. WONG, R.V. BUDNY, R. NAZIKIAN, Princeton Plasma Physics Laboratory, W.A. PEEBLES, T.L. RHODES, UCLA, R. PRATER, C.C. PETTY, General Atomics, R.J. JAYAKUMAR, LLNL — Core density pumpout has been observed on DIII-D during ECCD experiments with 3 MW of injected ECH power absorbed at $\rho < 0.3$ and 4 MW of counter neutral beam injection. The central plasma density dropped by almost 30% in 150 ms after ECH was turned on. FIR scattering data showed a strong increase of turbulence at $k_\theta \sim 7 \text{ cm}^{-1}$, approximately synchronous with this density pumpout. The fluctuation scale is intermediate between ρ_e and ρ_i ($k\rho_i \sim 4$). Mode identification (ITG, TEM [1] or other modes) is pending detailed data analysis. These results will be presented and compared with previously published data from TFTR [2] where a correlation between similar scale of turbulence and local electron energy transport was observed.
