Abstract Submitted for the DPP08 Meeting of The American Physical Society

Study of atmospheric air AC glow discharge using optical emission spectroscopy and near infrared diode laser cavity ringdown spectroscopy\textsuperscript{1} NIMISHA SRIVASTAVA, CHUJI WANG, Mississippi State University, Starkville, MS, THEODORE S. DIBBLE, State University of New York, Syracuse, NY — AC glow discharges were generated in atmospheric pressure by applying high voltage AC in the range of 3500-15000 V to a pair of stainless steel electrodes separated by an air gap. The discharges were characterized by optical emission spectroscopy (OES) and continuous wave cavity ringdown spectroscopy (cw-CRDS). The electronic (T\textsubscript{ex}), vibrational (T\textsubscript{v}), and rotational (T\textsubscript{r}) temperatures were measured. Spectral stimulations of the emission spectra of several vibronic bands of the 2\textsuperscript{nd} positive system of N\textsubscript{2}, the 1\textsuperscript{st} negative system of N\textsubscript{2}\textsuperscript{+}, the (0,1,2,3-0) bands of NO (A-X), and the (0-0) band of OH (A-X), which were obtained under various plasma operating conditions, show that T\textsubscript{r}, T\textsubscript{v}, and T\textsubscript{ex} are in the ranges of 2000 - 3800, 3500 - 5000, and 6000 - 10500K, respectively. Emission spectra show that OH concentration increases while NO concentration decreases with an increase of electrode spacing. The absorption spectra of H\textsubscript{2}O and OH overtone in the near infrared (NIR) were measured by the cw-CRDS with a telecommunications diode laser at wavelength near 1515 nm.
