Resonant Field Amplification in JET Advanced Regimes

MIKHAIL GRYAZNEVICH, UKAEA-EURATOM Fusion Association, Culham, UK, T.C. HENDER, Y. LIU, I.T. CHAPMAN, D. HOWELL, C.D. CHALLIS, UKAEA-EURATOM Fusion Association, E. JOFFRIN, R. KOSLOWSKI, JET-EFDA, Cilham, P. BURATTI, EURATOM-ENEA Fusion Association and JET-EFDA contributors — Resonant Field Amplification (RFA) has been systematically measured on JET, in two domains favourable for ITER steady-state operations: broad q-profiles with qmin 1 and qmin 2. MARS-F code modelling reproduces RFA data at low and high beta and suggests a new method of how the RFA data should be used to determine the no-wall limit experimentally. Although there is no strong evidence of a beta-limit connected with the RWM even at betaN 4 and performance was limited by internal n=1 modes, the observed (using RFA data) decrease in the no-wall limit with the increase in qmin is in agreement with the same dependence of the experimentally achieved highest beta values.

Funded by the United Kingdom Engineering and Physical Sciences Research Council and by the European Communities under the contract of Association between EURATOM and UKAEA.
