Ionization induced trapping in a laser wakefield accelerator
WILLIAM SCHUMAKER, C. MCGUFFEY, A.G.R. THOMAS, T. MATSUOKA, V. CHVYKOV, F.J. DOLLAR, G. KALINTCHENKO, V. YANOVSKY, A. MAKSIMCHUK, K. KRUSHELNICK, University of Michigan, V. YU. BYCHENKOV, P. N. Lebedev Physics Institute, I.V. GLAZYRIN, RFNC-VNIITF — Experimental measurements of electrons accelerated in a laser wake?eld accelerator indicate trapping initiated by an ionization mechanism. By using a range of noble gases and nitrogen as a very small percentage contaminant in helium gas, it is found that tunneling ionization of inner shell electrons plays an important role in determining the trapped charge. Although there is a small increase in electron number density due to the higher Z contaminant, it is shown to be insufficient to account for the increase in charge in the trapped bunch. The behavior of the trapping with laser intensity is also consistent with the tunnel-ionization thresholds for the gases used. This mechanism is likely to allow lower power laser systems to be used to generate comparably high-energy and low-emittance monoenergetic electron beams than in pre-ionized gas configurations. 2D particle-in-cell simulations including an ADK ionization model were used to correlate with experimental results.
