ROCCA, Colorado State University, N. ROHRINGER, F. STREITZ, J. WEISHEIT, F. GRAZIANI, LLNL — We present a new approach to determining stopping power of charged particles in plasmas. We will use short pulse laser-generated protons to heat solid slab targets. The high intensity, short duration laser pulse will generate a burst of protons that isochorically heat the sample, minimizing temperature and density gradients. A second laser-generated proton beam will be sent through the heated target and the relative energy loss will be measured using a proton spectrometer. The heated target thickness will be changed, providing a measure of  $dE/dx$ . The target conditions will be determined using Frequency Domain Interferometry for density and emissivity for temperature. The target thickness is varied, providing an avenue to determine the  $dE/dx$ . Preliminary experimental results will be presented.

<sup>1</sup>This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.
