Collisional Relaxation of a Strongly Magnetized, Two-Isotope, Pure Ion Plasma

C.Y. CHIM, T.M. O’NEIL, D.H.E. DUBIN, UCSD — The collisional relaxation of a strongly magnetized pure ion plasma that is composed of two species with slightly different mass is discussed. We assume the ordering $\Omega_{C1}, \Omega_{C2} \ll |\Omega_{C1} - \Omega_{C2}| \ll v/b$, where $\Omega_{C1}$ and $\Omega_{C2}$ are the two cyclotron frequencies, $v$ is the thermal velocity, and $b$ is the classical distance of closest approach. We find that the total cyclotron action for the two species $I_1$ and $I_2$ are adiabatic invariants conserved on the timescale of a few collisions, so the Gibbs distribution relaxes to the form $\exp[-H/T - \alpha_1 I_1 - \alpha_2 I_2]$, where $\alpha_1$ and $\alpha_2$ are thermodynamic variables like the temperature $T$. On a timescale longer than the collisional timescale, the two species share action so that $\alpha_1$ and $\alpha_2$ relax to a common value $\alpha$. During this process, $< I_1 > + < I_2 >$ remains constant. On an even longer timescale, the total action ceases to be a good constant of the motion and $\alpha$ relaxes to zero, yielding the usual Gibbs distribution $\exp[-H/T]$.
