Time-Dependent DIII-D Heat Transport Simulations Using Neural-Network Models[1] J.M. PENNA, Massachusetts Institute of Technology, S.P. SMITH, General Atomics, O. MENEGHINI, Oak Ridge Associated Univerities, C.J. LUNA, Arizona State University — The neural network transport model BRAINFUSE has been developed to produce transport fluxes based on local parameters [1]. The BRAIN-FUSE model has been integrated into the transport modeling framework ONETWO [2,3] in order to develop time dependent solutions and has been validated by artificially varying the input neutral beam power and comparing the output to DIII-D scans. These efforts have led to the development of a time-dependent workflow within the OMFIT integrated modeling framework. The new work flow can evolve the electron and ion temperatures as a function of time dependent sources and equilibria. The effects of different engineering parameters can be explored and optimized in support of DIII-D operations. The efficiency of this workflow enables planning plasma operations of next-day experiments, as will be required for ITER.
