Displacement energy of the surface layers of tungsten\textsuperscript{1} LONGTAO HAN, PREDRAG KRSTIC, SUNY at Stony Brook, NY 11794-5250 — A molecular dynamics study with BOP potential is used to calculate the threshold displacement energy (E\textsubscript{D}) of primary knock-on atoms in the surface layers of the tungsten bcc crystal lattice at 300 K and at various crystallographic directions. Depending on the direction, E\textsubscript{D} is 10\% to 75\% smaller from the bulk value at the first layer, interfacing vacuum, while it reaches close to the bulk value already at the third tungsten layer.
