Abstract for an Invited Paper
for the DPP16 Meeting of
the American Physical Society

Brilliant gamma-ray emission from near-critical plasma interaction with ultraintense laser pulses[1]

BIN QIAO, Peking University

γ-ray is the electromagnetic radiation having the highest photon energy and smallest wavelength, which has a broad range of applications in material science, nuclear physics, astrophysics and so on. In this talk, I shall report recent progresses [1-5] on theoretical and numerical studies of laser-driven brilliant gamma-ray radiation in near critical plasmas at Peking University (PKU), where an intense circularly polarized (CP) lasers. A novel resonant acceleration scheme can be achieved [1, 4] for generating dense relativistic electron bunches and emitting brilliant γ-ray pulses, where the laser frequency matches with that of electron betatron oscillation under quasistatic electromagnetic fields and radiation reaction in plasma. 3D PIC simulations show that brilliant γ-ray radiation with energy of 3J and brightness of 10^{24}photons/s/mm^2/mrad^2/0.1%BW (at 3MeV) can be produced by using CP lasers at intensity 10^{22}W/cm^2. It is found [3, 4, 5] that the total number of radiated photons scales as $a^2/S^{1/2}$ and the conversion efficiency scales as a^3/S, where $S = (n_e/n_c)a$ and a is the laser normalized amplitude. Further studies show [4,5] that if the laser intensity is increased to 10^{23}W/cm^2, the quantum electrodynamic (QED) effects are in favor of trapping and achieving resonance acceleration of electrons, resulting in production of brilliant γ-ray pulses with unprecedented power of 6.7PW and brightness of 10^{25}photons/s/mm^2/mrad^2/0.1%BW (at 15MeV). To the best of our knowledge, this is the γ-ray source with the highest peak brightness in tens-MeV regime ever reported in the literature. [1] B. Liu et al., PRL 110, 045002 (2013). [2] B.
