Striations in dual-frequency capacitively coupled CF₄ plasmas¹

YONG-XIN LIU, Dalian University of Technology, China, IHOR KOROLOV, Ruhr-University Bochum, Germany, EDMUND SCHUNGEL, Evatec AG, Switzerland, ZOLTAN DONKO, Hungarian Academy of Sciences, Hungary, JULIAN SCHULZE, Ruhr-University Bochum, Germany, YOU-NIAN WANG, Dalian University of Technology, China — Striations in dual-frequency (8/40 MHz) capacitively coupled CF₄ plasmas have been investigated by Phase Resolved Optical Emission Spectroscopy (PROES) and via particle in cell/Monte Carlo collision (PIC/MCC) simulations. The properties of the striated structures as a function of the high-frequency voltage amplitude, ϕ_H , have been analyzed. The measured spatiotemporal electronic excitation patterns at different ϕ_H showed good agreement with the simulation results. As ϕ_H increased, the width of each ion density peak increased, while the striation gap (i.e., the distance between adjacent ion density peaks) remained nearly unchanged, leading to a decrease in the number of striations and, finally, to their disappearance at a certain ϕ_H . In the presence of striations, the maximum ion density inside the bulk was found to increase slightly with ϕ_H , while the minimum ion density was almost independent of ϕ_H , as it is primarily determined by the lower excitation frequency, and is almost unaffected by ϕ_H . A hysteresis associated with the striated - DA (drift ambipolar) mode transition induced by increasing and decreasing ϕ_H has been observed both in the experiments and in the simulations.
