Determination of nuclear parton distribution functions and their uncertainties

SHUNZO KUMANO, KEK

Data of nuclear structure function F_2 and Drell-Yan cross-section ratios are analyzed for obtaining nuclear parton distribution functions, and their uncertainties are estimated by the Hessian method. Valence-quark distributions are determined well by the F_2 data in the large- x region. Their small- x behavior is constrained by baryon-number and charge conservations. Antiquark distributions are determined in the small- x region ($x \sim 0.01$) by the F_2 data and in the region $x \sim 0.1$ by the Drell-Yan data; however, their nuclear modifications are not obvious in the large- x region. Current data are not enough to determine nuclear gluon distributions because they have large uncertainties in the whole x region. A useful code could be obtained from our web site for calculating nuclear parton distribution functions.
