MIHARA, Osaka University, K. MINAMISONO, Michigan State University, T. YAMAGUCHI, Saitama University — We observed the alignment correlation terms in the $\beta$-ray angular distribution for $^8\text{Li}$ and $^8\text{B}$. The alignment correlation terms are useful probes to test the conserved vector current (CVC) hypothesis or the $G$-parity conservation in the $\beta$-decay process. The experiment was performed using the Van de Graaff accelerator at Osaka University. The pure nuclear-spin alignments were successfully produced by applying the $\beta$-NMR techniques and the alignment correlation terms were extracted from the $\beta$-ray angular distribution as a function of the $\beta$-ray energy. Under the assumption of the $G$-parity conservation, not only the weak magnetism (WM) but also the second-forbidden matrix element ($M_2$) of the vector current was obtained both from the present alignment correlation terms and the previous $\beta-\alpha$ angular correlation terms. The WM and $M_2$ are related by the CVC hypothesis to the $M_1$ and $E_2$ analog $\gamma$-decays from the isobaric analog state of $^8\text{Be}$. It is found that the $M_2$ is inconsistent with the previously observed $E_2\gamma$-decay.
