0+ states of the $^{12}$C nucleus: Faddeev calculation in configurations space

BRANISLAV VLAHOVIC, IGOR FILIKHIN, VLADIMIR SUSLOV, North Carolina Central University, Durham, NC 27707, US — The $\alpha$-cluster model and Faddeev equations in configuration space are applied to study the $^{12}$C nucleus. The model includes the Ali-Bodmer nuclear potential [1], attractive three-body potential, and takes into account the Coulomb interaction. An s-wave model [2] is adapted and parameters of the three-body potential are chosen to describe the first two 0+ levels of $^{12}$C. The value of the range parameter of the potential is adjusted to reproduce the position of diffraction minimum for the elastic form factor of $^{12}$C. The model assumes a strong distortion of the charge density of $\alpha$ clusters inside the $^{12}$C nucleus. It was found that the most probable configuration of the $\alpha$-clusters in the 0+1 state corresponds to an equilateral triangle with sides as large as 3.5 fm and in the 0+2 state to a linear chain with the values of 2.9 fm and 13.1 fm for each link. Having calculated low-lying levels of $^{12}$C, we found that the contributions of higher partial waves of nuclear interaction to the energy of 3$\alpha$-system are unnaturally large and some states turn to be overbound. Upon applying the method [3] based on the Pade approximation we got satisfactory description for the 0+3 and 0+4 states [4]. Additional 0+ broad resonance obtained in [3] was not found.
