$^{16}\text{O} + ^{16}\text{O}$ molecular structures of superdeformed bands in S isotopes

YASUTAKA TANIGUCHI, Nihon Institute of Medical Science — Structures of excited states in $^{33-36}\text{S}$ have been investigated by using the antisymmetrized molecular dynamics and the generator coordinate method (GCM). GCM basis wave functions are calculated by energy variation with a constraint on a quadrupole deformation parameter $\beta$. By performing GCM after parity and angular momentum projections, coexistence of positive- and negative-parity superdeformed (SD) bands are obtained, as well as low-lying states. The SD bands have structures of $^{16}\text{O} + ^{16}\text{O}$ + valence neutrons in molecular orbitals around two $^{16}\text{O}$ cores in a cluster picture.
