Excitations of metastable superfluid $^4$He at pressures up to 40 bars

JONATHAN PEARCE, Institut Laue-Langevin, France and University of Delaware, JACQUES BOSSY, Centre de Recherche sur les Très Basses Températures, France, HELMUT SCHOBER, Institut Laue-Langevin, France, HENRY GLYDE, University of Delaware, DAVID DAUGHTON, University of Delaware, NORBERT MULDERS, University of Delaware — We have performed neutron scattering measurements $^{[1]}$ of the fundamental excitations of liquid $^4$He confined in 44 Å pore diameter gelsil glass at pressures up to 40 bars in the wave vector range $0.4 < Q < 2.3 \text{ Å}^{-1}$. At pressures above 25.3 bars and at low temperature ($T = 0.4 \text{ K}$) the characteristic phonon-roton mode of superfluid $^4$He is no longer observed as a well-defined mode in the phonon-maxon region ($0.4 < Q < 1.6 \text{ Å}^{-1}$). Modes at wave vectors $Q > 1.6 \text{ Å}^{-1}$, especially the rotons, are observed up to complete solidification of all the liquid at $p \sim 40 \text{ bars}$, where the roton disappears. Simultaneous neutron diffraction measurements show the existence of Bragg peaks at and above 35.1 bars, indicating co-existence of liquid and solid in the pores at pressures $35 \leq p \leq 40 \text{ bars}$. These measurements are presented in conjunction with a measurement of the phase diagram of this system using ultrasound.
