**Quantum phase transitions in a novel Fermi-Bose Hubbard model**

LINCOLN D. CARR, JILA, University of Colorado at Boulder and National Institute of Standards and Technology, DANIEL E. SHEEHY, Physics Department, University of Colorado at Boulder, MURRAY J. HOLLAND, JILA, University of Colorado at Boulder and National Institute of Standards and Technology — We study a multi-band Fermi-Bose Hubbard model with on-site fermion-boson conversion and general filling factor in three dimensions. Such a Hamiltonian models an atomic Fermi gas trapped in a lattice potential and subject to a Feshbach resonance. We solve this Hamiltonian for paired fermions and bosons in the two state approximation at zero temperature. The problem then maps onto a coupled Heisenberg spin model. In the limit of large positive and negative detuning, the model correctly reproduces the quantum phase transitions in the Bose Hubbard and Paired-Fermi Hubbard models. Near resonance, the bosonic and fermionic Mott phases melt due to fluctuations between the two fields, giving rise to a total-number Mott state instead.
