MicroRaman Spectroscopy and Raman Imaging of Basal Cell Carcinoma

M.A. SHORT, X. K. CHEN, Department of Physics, Simon Fraser University, H. ZENG, Department of Cancer Imaging, British Columbia Cancer Agency, H. LUI, D. I. MCLEAN, Division of Dermatology, University of British Columbia, SFU TEAM, BCCA COLLABORATION, UBC COLLABORATION — We have measured the Raman spectra of normal and cancerous skin tissues using a confocal microRaman spectrograph with a sub-micron spatial resolution. We found that the Raman spectrum of a cell nucleolus is different from the spectra measured outside the nucleolus and considerably different from those measured outside the nucleus. In addition, we found significant spectroscopic differences between normal and cancer-bearing sites in the dermis region. In order to utilize these differences for non-invasive skin cancer diagnosis, we have developed a Raman imaging system that clearly demonstrates the structure, location and distribution of cells in unstained skin biopsy samples. Our method is expected to be useful for the detection and characterization of skin cancer based on the known distinct cellular differences between normal and malignant skin.
