Theory of Bubble Nucleation and Cooperativity in DNA melting

NIKOS VOULGARKIS, Theoretical Division, Los Alamos National Laboratory, SAUL ARES, Universidad Carlos III de Madrid, Madrid, Spain, KIM RASMUSSEN, Theoretical Division, Los Alamos National Laboratory, ALAN BISHOP, Theoretical Division, Los Alamos national Laboratory — The onset of intermediate states (denaturation bubbles) and their role during the melting transition of DNA are studied using the Peyrard-Bishop-Daxuois model by Monte Carlo simulations with no adjustable parameters. Comparison is made with previously published experimental results finding excellent agreement. Melting curves, critical DNA segment length for stability of bubbles and the possibility of a two states transition are studied. Excellent agreement with the experimental data is obtained.
