Breakdown of Strong Coupling Expansions for doped Mott Insulators

PHILIP PHILLIPS, UIUC, DIMITRIOS GALANAKIS, UIUC, TUDOR STANESCU, Rutgers University — We show that doped Mott insulators, such as the copper-oxide superconductors, are asymptotically slaved in that the quasiparticle weight, \( Z \), near half-filling depends critically on the existence of the high energy scale set by the upper Hubbard band. In particular, near half filling, the following dichotomy arises: \( Z \neq 0 \) when the high energy scale is integrated out but \( Z = 0 \) in the thermodynamic limit when it is retained. Slavery to the high energy scale arises from quantum interference between electronic excitations across the Mott gap.
