Diluted Magnetic Semiconductors based on Cr-doped InN

REKHA RAJARAM, 1,2, A NEY, 1,2, R.F.C. FARROW, 2, J.S. HARRIS, JR., 1, S.S.P. PARKIN, 2, 1) SOLID STATE AND PHOTONICS LAB, STANFORD UNIVERSITY, STANFORD, CA 94305 COLLABORATION, 2) IBM ALMADEN RESEARCH CENTER, SAN JOSE, CA 95120 COLLABORATION — Diluted magnetic semiconductors based on GaN have been widely studied following theoretical work that predicts room temperature ferromagnetism in these materials. However, there have been no reports yet of InN-based DMS materials. Here, we have studied the InN system doped with Cr and Mn. The films were grown on c-plane sapphire substrates by Plasma-Assisted MBE using a MOCVD-grown GaN buffer layer. X-Ray Diffraction rocking curve measurements confirmed single crystalline orientation with the FWHM of InN (0002) X-Ray rocking curve about 0.1° . PL measurements revealed a room-temperature bandgap of 0.8 eV and Hall measurements yield an n-type carrier concentration of about $5 \times 10^{19} \text{cm}^{-3}$ in both undoped InN as well as Cr-doped InN. While XRD measurements of the Mn-doped films reveal secondary phase formation, the Cr-doped films show no evidence of the formation of compounds such as CrN or Cr₂N. Magnetic measurements were made on the films using superconducting quantum interference device (SQUID) magnetometry. While the Cr-doped films show a clear magnetic hysteresis as well as remanence up to 300K, the Mn-doped films have less clear magnetic properties. Thus we present evidence of ferromagnetism in n-type, Cr-doped InN.
