The Resolution of the Domain Chaos Puzzle for Rotated Rayleigh-Bénard Convection

NATHAN BECKER, GUENTER AHLERS, UC Santa Barbara — Due to the Küppers-Lortz instability, Rayleigh-Bénard convection-patterns exhibit spatio-temporal chaos at the onset of convection when the sample rotates fast enough about a vertical axis. Previous work showed that the scaling of the correlation length \( \xi \) determined from the experimental chaotic patterns disagreed with the prediction from a Ginzburg-Landau weakly-nonlinear model. Commonly the power spectrum of the pattern images (the structure factor) is used to extract \( \xi \) from the half-width of its peak. Past experiments and simulations used standard Fourier techniques to calculate the power spectrum. On the basis of simulations using the Swift-Hohenberg equation, we show that those results are influenced strongly by the finite image-size available from experiment. The disagreement between experiment and theory was resolved by using the maximum-entropy method to calculate the power spectra. The maximum-entropy method is not as sensitive to the finite image-size effect. When applied to new experimental images, it yielded results for \( \xi \) that were in agreement with the theory.
