MgB$_2$; Al and C doping, $\sigma$-band filling and anisotropy reduction
SABINA RUIZ-CHAVARRIA, PABLO DE LA MORA, Depto. de Fis., Fac. de Ciencias, UNAM, Mexico, GUSTAVO TAVIZON, Depto. de Fis. y Quim. Teorica, Fac. de Quimica, UNAM, Mexico — Al and C-MgB$_2$ doping adds an electron to the system for each atom. This extra electron fills up the $\sigma$-bands thus diminishing the number of $\sigma$-carriers; this has been the usual explanation for the $T_c$ reduction. Nevertheless in this work we show that there is also a large reduction of anisotropy in the electrical conductivity due to the $\sigma$-carriers which should also have an effect on the $T_c$ reduction. Al and C doping produce a different $T_c$ pattern; this difference can be largely explained by the relative shift between the $\sigma$-bands and $\pi$-bands. After adjusting to this shift there is a small but visible difference, at low doping $T_c$ in the Al compounds drops faster than in the C compounds, this can be directly related to the faster loss of conductivity anisotropy in the Al compounds.
