Spin Glasses at the Bond Percolation Threshold\textsuperscript{1} EMILIANO MARCHETTI, STEFAN BOETTCHER, Physics Department, Emory University, Atlanta GA — Low energy excitations for the Edwards-Anderson model on hypercubic lattices at the bond percolation threshold $p_c$ are investigated. At $T = 0$, $p_c$ separates paramagnetic and spin glass phases. At the “edge” of the ordered state, these excitations are characterized by a distinct scaling exponent. This exponent allows to determine the shape of the phase boundary, $T_c(p) \sim (p - p_c)^\phi$, for $p \to p_c^+$, which is experimentally measurable in $d = 3$. At $p_c$, very large spin glass systems can be studied with an exact reduction algorithm\textsuperscript{2} to produce accurate scaling behavior.
