Combining DFT and Many-body Methods to Understand Correlated Materials¹

IGOR SOLOVYEV, National Institute for Materials Science, 1-2-1 Sengen, Tsukuba, Ibaraki 305-0047, Japan

Electronic and magnetic properties of strongly-correlated systems are typically controlled by a limited number of electronic states, located near the Fermi level and well isolated from the rest of the spectrum. This opens a formal way for combining the first-principles methods of electronic structure calculations, based on the density-functional theory (DFT), with model many-body methods, formulated in a restricted Hilbert space of states near the Fermi level. The core of this project is the construction of “*ab initio* model Hamiltonians”, which would incorporate the physics of on-site Coulomb correlations and provide a transparent physical picture for the low-energy properties of strongly-correlated systems. First, I will describe a systematic procedure for constructing such an effective Hubbard-type model, which consists of three major steps, starting from the electronic structure in the local-density approximation.¹ (i) Construction of the kinetic-energy part using an exact version of the downfolding method;^{1,2} (ii) Construction of the Wannier functions; (iii) Calculation of screened Coulomb interactions using a hybrid approach, which combines the random phase approximation with the constraint DFT.^{1,3} Then, I will illustrate abilities of this method for resolving a number of controversial issues, related with the interplay of the experimental lattice distortion and magnetic properties of four narrow t_{2g} band perovskite oxides (YTiO₃, LaTiO₃, YVO₃, and LaVO₃), for which the obtained Hamiltonian was solved using a number of techniques, including the Hartree-Fock (HF) approximation,⁴ the second-order perturbation theory and the t -matrix approach for the correlation energy,^{4,5} and a variational superexchange theory, which takes into account the multiplet structure of the atomic states.⁴ I will argue that the crystal distortion imposes a severe constraint on the form of the possible orbital states, which favors the formation of experimental magnetic structures in YTiO₃, YVO₃, and LaVO₃, even at the level of HF approximation. The correlation effects systematically improve the agreement with the experimental data and additionally stabilize the experimentally observed G- and C-type antiferromagnetic states in YVO₃ and LaVO₃. The role of relativistic spin-orbit interaction will be also discussed.
