The geometrically-averaged density of states as a measure of localization

RACHEL WORTIS, YUN SONG, WILLIAM ATKINSON, Trent University — Motivated by current interest in disordered systems of interacting electrons, we examine the use of the geometrically-averaged density of states, $\rho_\text{g}(\omega)$, as an order parameter for the Anderson transition. In infinite systems, when $\rho_\text{g}(\omega)$ vanishes, while the density of states remains nonzero, the states at energy $\omega$ are localized. In the context of noninteracting finite-size systems we show that a finite energy resolution, a common feature of many-body calculations, changes the scaling of $\rho_\text{g}(\omega)$ such that the critical disorder is over-estimated. Furthermore we demonstrate that even in infinite systems a decline in $\rho_\text{g}(\omega)$ with increasing disorder strength is not uniquely associated with localization.
